The anaerobic bioreactor, which was the source of the biomass investigated in this study, was previously described by O'Reilly et al. . Briefly, the bioreactor had a working volume of 3.5 l and was operated at 15°C for 300 days to treat a synthetic, glucose-based wastewater, which was buffered at pH 7.1 with NaHCO₃. Samples of sludge granules for phylogenetic and metaproteomic analyses were obtained at the conclusion of the trial (day 300).

The putative functions of the proteins detected in the anaerobic bioreactor were related to cellular processes, including methanogenesis from CO₂ and acetate, glycolysis and the pentose phosphate pathway. Metaproteomics also indicated, by protein assignment, the presence of specific micro-organisms in the bioreactor.

About the Practical Course Anaerobic microbiology is a key research field to address present and future challenges in industry and society. Anaerobic microbes turn waste products into biogas and biofuels, they are responsible for many steps in the elemental C-, N- and S-cycles and they form the human and animal's gut microbiomes.

Obligate anaerobic bacteria must be grown under conditions devoid of oxygen. The most common approach is culture in an anaerobic jar (Figure). Anaerobic jars include chemical packs that remove oxygen and release carbon dioxide (CO₂). An anaerobic chamber is an enclosed box from which all oxygen is removed.
